ABSTRACT:

CHG DATE=19990617 STATUS=O>The new process produces fuel gas from organic materials, especially wood and other biomass. These are pyrolysed, producing low temperature carbonisation gas It contains hydrocarbons, tar and water vapour removed with thermal decomposition. The residue is a char containing inorganic matter. The resultant gas is burned rich, at temperatures of 1200 deg C and above. Resultant hot gas is used to gasify the char, producing dust-laden synthesis gas, which is then cleaned. Novel features include

removal of the low temperature carbonisation gas with minimal dust loading. Its subsequent combustion is only partial, under conditions of imposed vorticity. Also claimed is a plant to carry out the process described.

ABSTRACTED-PUB-NO: DE19618213A

BASIC-ABSTRACT: The new process produces fuel gas from
organic materials,
especially wood and other biomass. These are pyrolysed,
producing low
temperature carbonisation gas It contains hydrocarbons, tar
and water vapour
removed with thermal decomposition. The residue is a char
containing inorganic
matter. The resultant gas is burned rich, at temperatures
of 1200 deg. C and
above. Resultant hot gas is used to gasify the char,

producing dust-laden
synthesis gas, which is then cleaned. Novel features
include removal of the
low temperature carbonisation gas with minimal dust
loading. Its subsequent
combustion is only partial, under conditions of imposed
vorticity. Also
claimed is a plant to carry out the process described.

USE - To produce gas from organic materials e.g. wastes and
biomass.

ADVANTAGE - A high grade fuel or synthesis gas is produced
in this process.
Minimal dust is removed from the pyrolysis stage, reducing
the quantity of
slagging matter reaching the rich combustion stage,
avoiding operational
difficulties. Maximum temperatures of 1500 deg. C are
reached. Steam
injection introduces the water gas shift reaction, and
controls the
temperatures below excessive levels, whilst enhancing the
hydrogen and carbon
monoxide content.
